

Both panels show the same raw signed geo-branch Ridge coefficient β of the W1 response (area-data design: masking an LSOA replaces all of its inputs with the training median; N=4,000, seed 42); only the colour scheme differs. Higher β = higher relative contribution to the coalition W1 response; the sign does NOT indicate whether predicted crime rises or falls. No absolute values are taken. Scales run from the minimum β (-1.33) to its 98th percentile (+4.22); higher units are capped (arrow). Model sensitivity, not causal effects.
